

Water Year 2020 Climate Summary for Arches National Park

Matthew Van Scoyoc

2020-11-03

This document summarizes current temperature and precipitation anomalies relative to 30-year (1981-2010) averages for Arches National Park (ARCH) during the 2020 water year (October 2019 through September 2020). The data for these analyses were collected at the Visitor Center Co-op Station by NPS personnel and downloaded from the [Global Historical Climatology Network](#) on 26 October, 2020 using R (ver. 4.0.3, R Core Team, 2020) and the rnoaa package (ver 1.2.0, Chamberlain, et al. 2020). The data used for these analyses include the daily high temperature (TMAX), daily low temperature (TMIN), and daily precipitation accumulation (PRCP). Averages were calculated using the mean for the period of interest.

Temperature

Water year 2020 was the 18th warmest water year in the 40-year record for ARCH (1980 to 2020); the average annual temperature was 0.28°C above the 30-year average (figure 1A). The annual average daily high was 0.37°C below the 30-year average (figure 1B). The monthly average daily high exceeded the 30-year monthly average 7 times (Nov, Mar, Apr, May, Jun, Aug, and Sep; figure 1C). The annual average daily low (TMIN) was 1.08°C above average (figure 1B). The monthly average daily low exceeded the 30-year monthly average 9 times (Dec, Jan, Mar, Apr, May, Jun, Jul, Aug, and Sep; figure 1C).

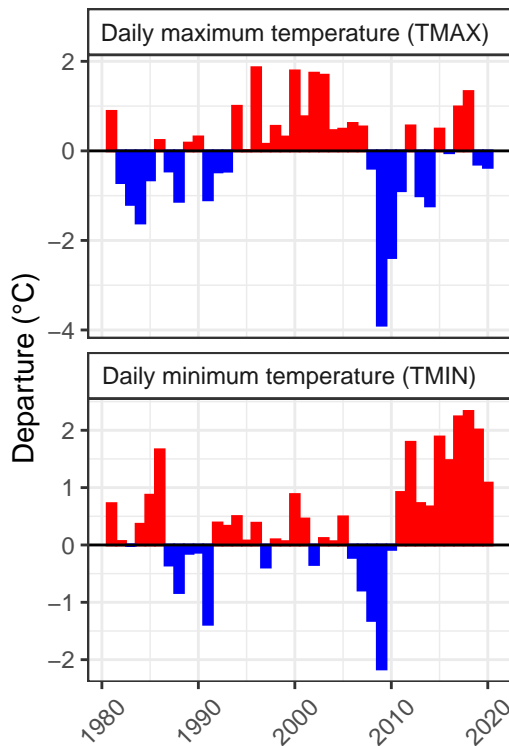

Precipitation

Water year 2020 was the 2nd driest on record for ARCH (figures 2A and 2B). Total precipitation was 146.6 mm less than the 30-year average, totaling 74.9 mm. Nov, Dec, and Jun received above average precipitation, but were not enough to compensate for the 9 months that were below average (Oct, Jan, Feb, Mar, Apr, May, Jul, Aug, and Sep; figures 2B and 2D).
